## 1 Information retrieval metrics

In the field of information retrieval (IR), the goal is to identify documents from a large collection that are most relevant to a user's query. If the subset of relevant documents is known, we can evaluate the quality of an information retrieval method using the metrics of *precision*, *recall*, *accuracy*, *fallout* and the *F*-measure (harmonic mean of *precision* and *recall*). To define these metrics we need to determine the true positives (*tp*), false positives (*fp*), true negatives (*tn*), and false negatives (*fn*) achieved by the retrieval method. These are defined by the cross-tabulation between relevance and retrieval: *true positives* comprise documents that are both relevant to the query and retrieved by the method; *false positives* are documents retrieved but irrelevant; *false negatives* are relevant but not retrieved; and *true negatives* include all irrelevant documents not retrieved by the method.

In the case of synonym thesauri, all the synonym pairs happening in the processed thesauri can be grouped into four categories similarly: *true positives* which refer to synonym pairs that occur in both a given thesaurus and a given corpus, *false positives* which occur in the thesaurus but not the corpus, *false negatives* which occur in the corpus but not the thesaurus (but perhaps in *some other* thesaurus), and *true negatives* which occur in neither the thesaurus nor the corpus. As discussed in the main text, such a simple transfer

of definition to ontology has issues. However we computed the following IR metrics based on these definitions, mainly for a comparison with our proposed ontology-evaluation metrics.

Based on the above definitions, some common metrics used in IR are defined as follows:

$$\text{Precision} \stackrel{\text{def}}{=} \frac{N_{tp}}{N_{tp} + N_{fp}}, \quad (1)$$

$$\text{Recall} \stackrel{\text{def}}{=} \frac{N_{tp}}{N_{tp} + N_{fn}}, \quad (2)$$

$$\text{Accuracy} \stackrel{\text{def}}{=} \frac{N_{tp} + N_{tn}}{N_{tp} + N_{tn} + N_{fp} + N_{fn}}, \quad (3)$$

$$\text{Fallout} \stackrel{\text{def}}{=} \frac{N_{fp}}{N_{fn}}, \quad (4)$$

$$F \stackrel{\text{def}}{=} 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}}, \quad (5)$$

$$F_\beta \stackrel{\text{def}}{=} (1 + \beta^2) \cdot \frac{\text{Precision} \cdot \text{Recall}}{(\beta^2 \cdot \text{Precision} + \text{Recall})}. \quad (6)$$

$F_\beta = F$  when  $\beta = 1$ .  $F_2$  weights recall twice as much as precision and  $F_{\frac{1}{2}}$  weights precision twice as much as recall. The results are listed in Table 2 in the *Results* section.

## 2 Novel metrics for evaluating ontology fitness

For a given reference corpus  $T$ , we define the *complete ontology*  $\mathcal{O}(\mathcal{C}_T, \mathcal{R}_T)$  which incorporates all  $N$  concepts encountered in the corpus and all the relations between them. We also derive from the corpus  $T$ , a frequency  $f_i$  for each concept in  $\mathcal{C}_T$  and an association probability  $p_{ij}$  for each relation in  $\mathcal{R}_T$ .  $f_i$  should be normalized in such a way that  $\sum_{i \in \mathcal{C}_T} f_i = \sum_{i=1}^N f_i = 1$  and by definition (See section one),  $p_{ij}$  is normalized so that  $\sum_{j=1}^{M_i} p_{ij} = 1$  for a given concept  $i$ . In implementation, we (under)approximate the complete

ontology (thesaurus) with the union of thesauri, excluding concepts and relations not found in the corpus.

To evaluate an arbitrary ontology,  $X = \{C_X, R_X\}$ , regarding to corpus  $T$ , we can identify sets  $C_X(tp)$ , and  $R_X(tp)$ , such that  $C_X(tp) = C_X \cap \mathcal{C}_T$ , and  $R_X(tp) = R_X \cap \mathcal{R}_T$ .

This allows us to replace integer  $N_{tp}$  with real-valued weight  $W_{C_X(tp)}$  such that

$$W_{C_X(tp)}(T) \stackrel{\text{def}}{=} \sum_{i \in C_X(tp)} f_i, \quad (7)$$

If we expand this measure to also account for relation importance, it becomes

$$W_{C_X(tp) R_X(tp)}(T) \stackrel{\text{def}}{=} \sum_{i \in C_X(tp)} \sum_{j \in C_X(tp)} \sum_{k(i) \in R_X(tp)} f_i p_{k|ij}, \quad (8)$$

where  $p_{k|ij}$  is equal to the association probability between concepts  $i$  and  $j$ ,  $p_{ij}$ , if a relation between them exists in  $X$ , and is zero otherwise.

Similarly we define  $C_X(fn) = C_T - C_X(tp)$  and  $R_X(fn) = R_T - R_X(tp)$  and get

$$W_{C_X(fn) R_X(fn)}(T) \stackrel{\text{def}}{=} \sum_{i \in C_X(fn)} \sum_{j \in C_X(fn)} \sum_{k \in R_X(fn)} f_i p_{k|ij}, \quad (9)$$

Now we are able to introduce our first ontology-evaluation measure –*breadth*– to capture the theoretical coverage of an ontology:

$$Breadth_X^2(T) \stackrel{\text{def}}{=} \frac{\sum_{i \in C_X(tp)} \sum_{j \in C_X(tp)} \sum_{k \in R_X(tp)} f_i p_{k|ij}}{\sum_{i' \in C_X(tp)} \sum_{j' \in C_X(tp)} \sum_{k' \in R_X(tp)} f_{i'} p_{k'|i'j'} + \sum_{i'' \in C_X(fn)} \sum_{j'' \in C_X(fn)} \sum_{k'' \in R_X(fn)} f_{i''} p_{k''|i''j''}} \quad (10)$$

Because every concept and its relations in a corpus either happen in the ontology ( $tp$ ) or not ( $fn$ ), equation (10) can be simplified as follows:

$$\begin{aligned}
\text{Breadth}_X^2(T) &= \frac{\sum_{i \in C_X(tp)} \sum_{j \in C_X(tp)} \sum_{k \in R_X(tp)} f_i p_{k|ij}}{\sum_{i' \in C_T} \sum_{j' \in C_T} \sum_{k' \in R_T} f_{i'} p_{k'|i'j'}} \\
&= \frac{\sum_{i \in C_X(tp)} \sum_{j \in C_X(tp)} \sum_{k \in R_X(tp)} f_i p_{k|ij}}{\sum_{i' \in C_T} \sum_{j' \in C_T} f_{i'} \sum_{k' \in R_T} p_{k'|i'j'}} \\
&= \sum_{i \in C_X(tp)} \sum_{j \in C_X(tp)} \sum_{k(i) \in R_X(tp)} f_i p_{k|ij} \tag{11} \\
&= W_{C_X(tp) R_X(tp)}(T). \tag{12}
\end{aligned}$$

This approach of weighing importance works as intended for  $N_{tp}$  and  $N_{fn}$ , but not for  $N_{fp}$  and  $N_{tn}$  because the corresponding  $f_i$ 's all equal zero in the corpus.

We can further modify this measure of theoretical coverage to account also for parsimony, and thus develop a general measure of *Depth* of ontology  $X$  with respect to corpus  $T$ :

$$\begin{aligned}
\text{Depth}_X^2(T) &\stackrel{\text{def}}{=} \frac{\text{Breadth}_X^2(T)}{\text{Number of relations in } X} \tag{13} \\
&= \frac{\sum_{i \in C_X(tp)} \sum_{j \in C_X(tp)} \sum_{k \in R_X(tp)} f_i p_{k|ij}}{|R_X|}. \tag{14}
\end{aligned}$$

In the case of an ontology, *Depth* translates into the average probability mass (in a corpus) for each concept relation. Large ontologies would tend to have a better value of *Breadth*, but not necessarily a better *Depth*. This is because a large ontology may be padded with very rare concepts and relations lowering its fit to the corpus compared to a small ontology containing only the most frequent ones.

Finally, we can create a more general measure  $\text{Depth}_\beta$  that allows flexibility in the specification of ontological coverage and parsimony, such that

$$\text{Depth}_{X,\beta}(T) = \frac{[\text{Breadth}_X]^{(2-\beta)}}{|R_X|^\beta} \tag{15}$$

In implementation, we tried  $\beta = 0.5, 0.75, 1.5$  for this equation. The results are presented in Table 2 of the *Results* section.

### 3 The fittest ontology of given size

We can then define the *fittest ontology of fixed size*,  $\mathcal{O}_{c,r} \left( T, C, R, \left\{ f_i, \{p_{ij}\}_{j=1,\dots,M'_i} \right\}_{i=1,\dots,c} \right)$  with a predetermined  $c$  concepts and  $r$  relations ( $r = \sum_{i \in c} M'_i$ ) such that  $C \subset \mathcal{C}_T$ ,  $R \subset \mathcal{R}_T$ , and  $Breadth_{\mathcal{O}_{c,r}}(T)$  is maximized over all possible sets  $C$  and  $R$  of sizes  $c$  and  $r$ , correspondingly.

For an arbitrary ontology  $O_{c,r}$ , we would like to benchmark it using the fittest ontology of the same size,  $\mathcal{O}_{c,r}$ . Once we have estimated its  $Breadth_{O_{c,r}}$  and  $Depth_{O_{c,r}}$  for a given corpus  $T$ , we can compute the *loss measures* relative to its fittest counterpart:

$$\text{Breadth Loss}_{O_{c,r}}(T) = Breadth_{O_{c,r}}(T) - Breadth_{\mathcal{O}_{c,r}}(T), \quad (16)$$

$$\text{Depth Loss}_{O_{c,r}}(T) = Depth_{O_{c,r}}(T) - Depth_{\mathcal{O}_{c,r}}(T). \quad (17)$$

To ease computation, we can define simplified versions of these measures that constrain only the number of relations,  $r$ :

$$\text{Breadth Loss}_{O_{*r}}(T) = Breadth_{O_{*r}}(T) - Breadth_{\mathcal{O}_{*r}}(T), \quad (18)$$

$$\text{Depth Loss}_{O_{*r}}(T) = Depth_{O_{*r}}(T) - Depth_{\mathcal{O}_{*r}}(T), \quad (19)$$

where  $*$  indicates that  $c$  is not constrained. These results are also summarized in Table 2.

The strength of the loss measure is its ability to compare a specific ontology to the *Depth*-optimized ontology of the same size, rather than one significantly larger or smaller. In theory, this could allow us to benchmark ontologies covering domains for which there may be no competing ontologies. The challenge with this in practice is that if there are no competing ontologies, then there is no superset of concepts and relations from which to draw into an optimal  $\mathcal{O}_{c,r}$  other than  $O_{c,r}$  itself. If we wanted to prune an ontology of its weakest parts, however, we could obtain the fittest sub-ontology  $\mathcal{O}_{\gamma,\phi}$ , by specifying  $\gamma$  concepts and  $\phi$  relations so that the *Depth* reaches its maximum for the given  $\gamma$  and  $\phi$ .

### 4 Comparing corpora

In addition to comparing ontologies relative to the corpora they describe, we can compare different corpora with respect to one or more ontologies. Let  $T_1$  and  $T_2$  indicate two distinct

corpora, such as 19th Century English novels and 20th Century scholarly medical articles. We can define the *distance* between the two corpora with respect to headword  $h_i$  and its  $M_i$  synonyms by calculating the Minkowski distance with corpora-specific parameter estimates  $p_{ij}$  in the following way.

$$d_{T_1, T_2}(h_i) \stackrel{\text{def}}{=} \left[ \sum_{j=1}^{M_i} |p_{ij}^{(T_1)} - p_{ij}^{(T_2)}|^r \right]^{\frac{1}{r}}. \quad (20)$$

Or

$$d_{T_1, T_2}(h_i) \stackrel{\text{def}}{=} \left[ \sum_{j=1}^{M_i} |f_i^{(T_1)} p_{ij}^{(T_1)} - f_i^{(T_2)} p_{ij}^{(T_2)}|^r \right]^{\frac{1}{r}}. \quad (21)$$

In our practical implementations of this measures (we used both of the above equations in our practical experiments), we used  $r = 1$  (the Manhattan distance), and  $r = 2$  (the Euclidean distance).

The three-way distance for three corpora,  $T_1$ ,  $T_2$ , and  $T_3$  is then just a sum of three pairwise distances.

$$d_{T_1, T_2, T_3}(h_i) \stackrel{\text{def}}{=} d_{T_1, T_2}(h_i) + d_{T_1, T_3}(h_i) + d_{T_2, T_3}(h_i). \quad (22)$$

In our three-corpus example, the most interesting headwords to visualize are those with maximum  $d_{T_1, T_2, T_3}(h_i)$ , which have the substitution probability estimates most unlike each other across the three corpora.

We can also define the overall distance between two corpora.

$$D_{T_1, T_2} \stackrel{\text{def}}{=} \sum_{i=1}^N d_{T_1, T_2}(h_i). \quad (23)$$

With this approach, we can compute a taxonomy or phylogeny of several corpora using a distance-matrix to construct the tree.

We can also calculate the entropy of synonyms in corpus  $T$  in bits. This captures the ambiguity or linguistic richness of a corpus with respect to a thesaurus.

$$H_T \stackrel{\text{def}}{=} - \sum_{i=1}^N f_i^{(T)} \sum_{j=1}^{M_i} p_{ij}^{(T)} \log_2 p_{ij}^{(T)}. \quad (24)$$

Finally, for symmetry, we can whimsically imagine the generation of a nonsense *fittest* corpus, which is completely consistent with a given ontology or thesaurus. That such a corpus would tend to be very redundant (or very small) highlights the limited representation most ontologies and thesauri provide of their domains, but also the collective importance of low-frequency relationships in modeling them.

## 5 Data

We used three very different corpora to illustrate our approaches.

1) *Medicine*: Clinical journal article abstracts from PubMed database. Based on the clinical queries service offered by PubMed (<http://www.ncbi.nlm.nih.gov/corehtml/query/static/clinicaltable.html>), we generated a modified query:

```
((clinical[Title/Abstract] AND trial[Title/Abstract]) OR
clinical trials[MeSH Terms] OR clinical trial[Publication Type] OR
random*[Title/Abstract] OR random allocation[MeSH Terms] OR
therapeutic use[MeSH Subheading]) OR (sensitiv*[Title/Abstract]
OR sensitivity and specificity[MeSH Terms] OR
diagnos*[Title/Abstract] OR diagnosis[MeSH:noexp] OR
diagnostic * [MeSH:noexp] OR diagnosis,differential[MeSH:noexp] OR
diagnosis[Subheading:noexp])
```

By limiting ourselves only to English abstracts in the core clinical journals for the whole period covered by PubMed, up to Feb 25, 2009, we downloaded 786,180 clinical medicine-related abstracts.

2) *News*: Reuters News corpus

The Reuters corpus covered news stories between 08/20/1996 and 08/19/1997.

3) *Literature*: 19th century literature – written in English or translated to English. We compiled a subjective list of the 50 best books of the 19th century based on the information from [http://www.goodreads.com/list/show/16.Best\\_Books\\_of\\_the\\_19th\\_Century](http://www.goodreads.com/list/show/16.Best_Books_of_the_19th_Century).

We then obtain the flat text files of these books from [www.gutenberg.org](http://www.gutenberg.org) (see Table 1).

Table 1: Contents of the *Literature* corpus.

<i>Title</i>	<i>Author</i>	<i>English translator</i>
Emma	Austen, Jane	
Mansfield Park	Austen, Jane	
Northanger Abbey	Austen, Jane	
Persuasion	Austen, Jane	
Pride and Prejudice	Austen, Jane	
Title Sense and Sensibility	Austen, Jane	
The Tenant of Wildfell Hall	Bront, Anne	
Jane Eyre	Bront, Charlotte	
Villette	Bront, Charlotte	
Wuthering Heights	Bront, Charlotte	
Alice’s Adventures in Wonderland	Carroll, Lewis	
Through the Looking-Glass	Carroll, Lewis	
The Awakening and Selected Short Stories	Chopin, Kate	
The Woman in White	Collins, Wilkie	
Heart of Darkness	Conrad, Joseph	
A Christmas Carol	Dickens, Charles	
A Tale of Two Cities	Dickens, Charles	
Bleak House	Dickens, Charles	
David Copperfield	Dickens, Charles	
Great Expectations	Dickens, Charles	
Little Dorrit	Dickens, Charles	
Our Mutual Friend	Dickens, Charles	
Crime and Punishment	Dostoyevsky, Fyodor	Garnett, Constance
The Brothers Karamazov	Dostoyevsky, Fyodor	Garnett, Constance

Notes from the Underground	Dostoyevsky, Fyodor	unknown
A Study in Scarlet	Doyle, Arthur Conan, Sir	
The Count of Monte Cristo	Dumas pre, Alexandre	
Madame Bovary	Flaubert, Gustave	Aveling, Eleanor Marx
Far from the Madding Crowd	Hardy, Thomas	
Tess of the d'Urbervilles	Hardy, Thomas	
The Mayor of Casterbridge	Hardy, Thomas	
The Scarlet Letter	Hawthorne, Nathaniel	
Les Misrables	Hugo, Victor	Hapgood Isabel Florence
A Doll's House	Ibsen, Henrik	
Moby Dick, or, the whale	Melville, Herman	
Frankenstein	Shelley, Mary Wollstonecraft	
Treasure Island	Stevenson, Robert Louis	
Dracula	Stoker, Bram	
Vanity Fair	Thackeray, William Makepeace	
Anna Karenina	Tolstoy, Leo, graf	Garnett, Constance
War and Peace	Tolstoy, Leo, graf	Maude, Aylmer Maude, Louise Shanks
A Connecticut Yankee in King Arthur's Court	Twain, Mark
