Appendix A

Statistical methods

Despite efforts to collect as complete and comprehensive data as possible on global consumption levels of SSBs, fruit juices, milk, and calcium, data in some countries were not available. To account for these missing data, we used an age-integrating Bayesian hierachial model, DisMod3, developed as part of the Global Burden of Disease 2010 project (1). This model pooled data from multiple sources and modeled missing data using informative time-varying covariates, borrowing information across geographical region and time period while also incorporating uncertainty due to measurement error and model specification. The model was fit using a randomized Markov Chain Monte Carlo (MCMC) algorithm based on the Adaptive Metropolis step function and estimated fixed effects for study-specific and national-level covariates and random effects for GBD region and country. The MCMC was implemented in the PyMC Python module(2) to generate 1000 draws of dietary intake for each country-age-sex strata after discarding iterations from the burn-in convergence period. Goodness-of-fit was assessed using a hold-out cross-validation approach, as described elsewhere (1, 3, 4). Across all 1000 simulations for a given country, year, sex combination, we used the median value and 2.5 and 97.5 percentile of each set of draws of dietary intake as the estimate and the upper and lower confidence intervals for this outcome. The model outputs estimates of dietary intakes for both men and women in single year age groups for 1990 and 2010 for 187 countries worldwide.

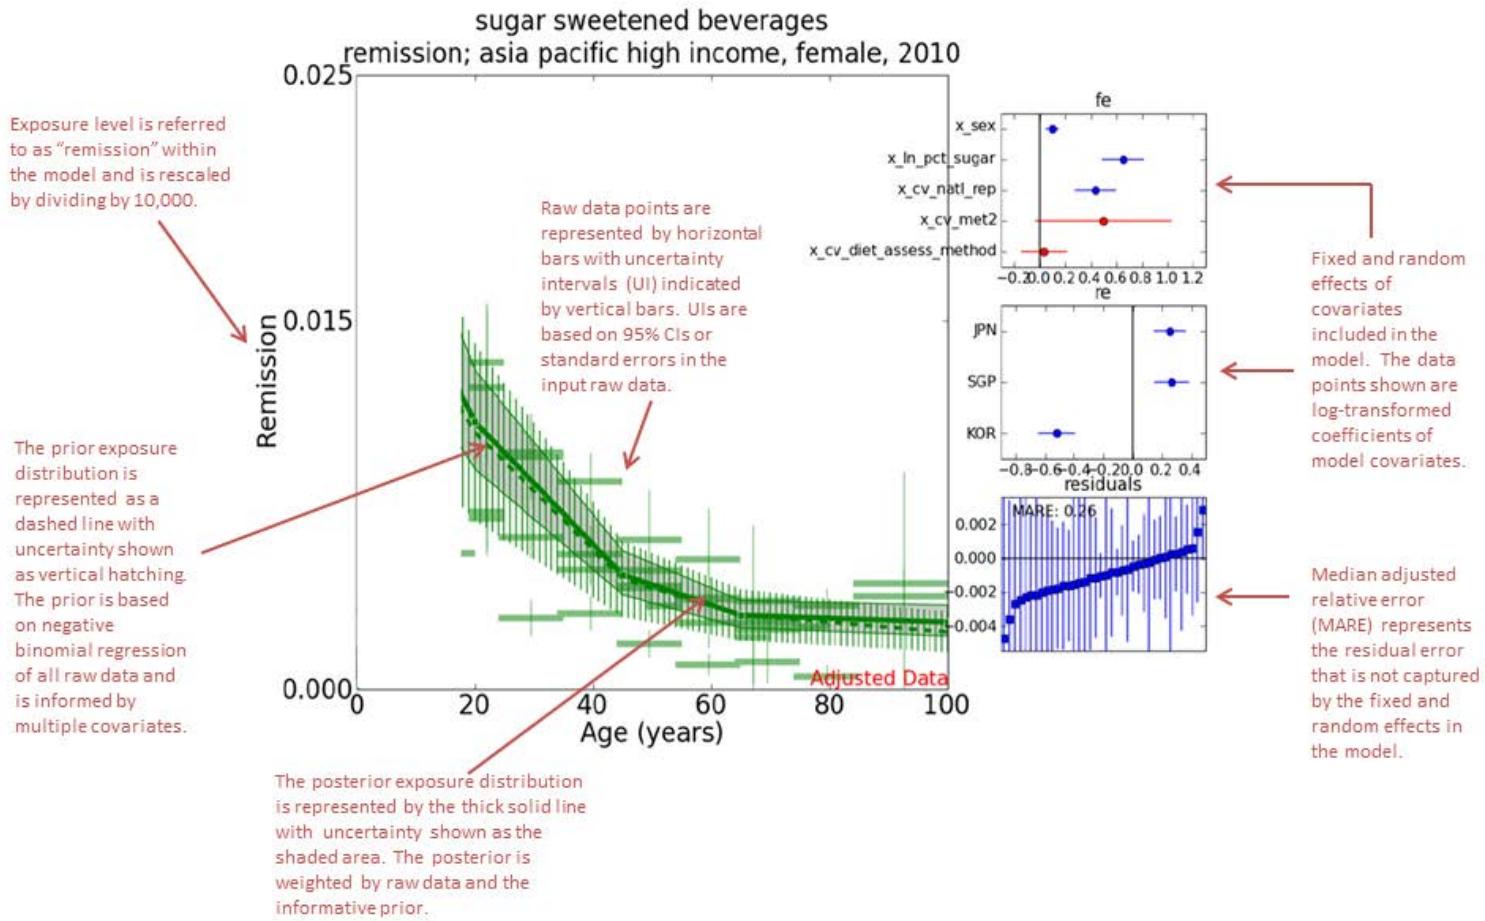

Both study-specific and national-level covariates were included in the model. The study-specific covariates accounted for inconsistencies in the raw data; for example, data that are subnational (rather than nationally representative), or data collected using less-optimal methods. These study-specific covariates are indicator variables used in the model to adjust data collected using less-optimal methods to the level consistent with those of the gold standard data. For sugar-sweetened beverages, three

study-specific indicator variables were used to indicate the quality of measurement method and the national representativeness of the data. In collecting dietary data, diet records, recalls, and FFQs provided estimates of individual-level consumption and are therefore the gold-standard methods, while household availability/budget surveys estimate food intake/expenditure at the household level and are therefore less-optimal. The first study-specific variable indicates whether the data were collected using the optimal methods of diet records, recalls, or FFQs or the sub-optimal methods of household availability/budget surveys. The second study-specific variable denotes whether the data were collected based on the optimal definition of the exposure: total intake of any sugar-sweetened beverage with ≥ 50 kcal per 8 oz (226.8 grams) serving, including carbonated beverages, soft drinks, sodas, energy drinks, fruit drinks etc.) or a suboptimal metric. The third is an indicator variable for whether the data are from non-nationally-representative studies/surveys. In addition, we allowed the variance of sub-national-level data to be different from nationally-representative data.

Country-level data on food availability was used in the model to inform the global and country-level trends. We used data from the Food Balance Sheets of the Food and Agriculture Organization of the United Nations (FAO) which captures a country's annual food availability for human consumption based on reported local production, imports, and exports, adjusted for other uses (livestock, seed) (5). We used the FAO food balance sheets to construct a variable that measures the annual food availability per capita for sugars, by combining: sugar and sweeteners, sugar (raw equivalent), sugar beet, sugar cane, non-centrifugal sugar, and sugarcrops. Table S1 presents the effect size estimated for the study-level and national covariates from the DisMod3 model. Figure S1 provides an example of DisMod3 region-level outputs.

Appendix A Table 1. Effect sizes and standard errors for study-level and national covariates

Covariate	Effect size mean	Effect size SE
Study level covariates		
Suboptimal dietary assessment method	0.001	0.096
Suboptimal exposure definition	0.213	0.278
Non-nationally representative data	0.459	0.086
Sex	0.088	0.029
National covariates		
Log per capita sugar availability based on FAO data	0.789	0.123

Appendix A Figure. Graphical representation and explanation of region-level outputs of the Bayesian hierarchical model. Results for women in the high-income Asia Pacific region in 2010 are shown as an example.

Country	Study name	Time period	Age range (years)	Sample size	Percent female	Coverage	Diet assessment method	Sampling method
United Kingdom	Dietary and Nutritional Survey of British Adults	1986-1987	20-64	2197	50.5	national	single short-term diet recall	multi-stage sampling
United Kingdom	National Diet and Nutrition Survey: people aged 65 years and over	1994-1995	65-100	1275	50.4	national	single short-term diet recall	one-stage sampling
United Kingdom	National Diet and Nutrition Survey: adults aged 19-64 years	2000-2001	20-64	1724	55.6	national	single short-term diet recall	multi-stage sampling
United States of America	NHANES 2003-2006	2003-2006	20-85	17150	52.4	national	multiple short term diet recall	multi-stage sampling

Table B. Country-level mean consumption of fruit juice, milk, and sugar-sweetened beverages for men and women in 2010.

Country	Sex	Midpoint of age range	Mean juice intake (servings/day)	Juice, lower uncertainty interval	Juice, upper uncertainty interval	Mean milk intake (servings/day)	Milk, lower uncertainty interval	Milk, upper uncertainty interval	Mean SSB intake (servings/day)	SSB, lower uncertainty interval	SSB, upper uncertainty interval	Mean calcium intake (servings/day)	Calcium, lower uncertainty interval	Calcium, upper uncertainty interval
