[^0]
[^0]:    ${ }^{1}$ Iso-synonymous codons are recognized by the same tRNA species. The perfect-match rule states that perfect codon-anticodon matches are favored over imperfect matches. The stability rule assumes that a codon-anticodon interaction is stable if the codon has either 1 or 2 G/C and is otherwise unstable (Rocha 2004 Genome Res 14, 2279). This rule claims that codons with stable interactions with anticodons are preferred. We denote a star (correct prediction) or cross (incorrect prediction) for cases where the predictions of the two rules are compatible with each other.
    ${ }^{2}$ Perfect codon-anticodon matches are denoted by 1 and imperfect matches are denoted by 0 .
    ${ }^{3}$ Stable codon-anticodon interactions are denoted by 1 and unstable interactions are denoted by 0 .
