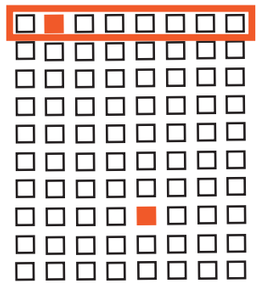
The presence of multimorbidity (≥2 conditions) varies depending on the conditions considered in the count

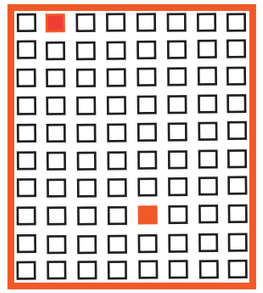
In an example single person:

multimorbidity **is not present**



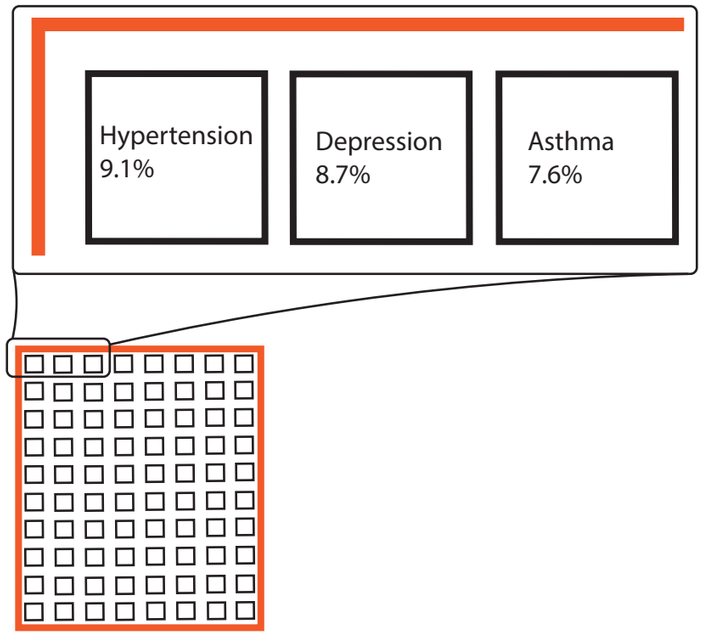
when 8 conditions are considered

but, multimorbidity **is present**

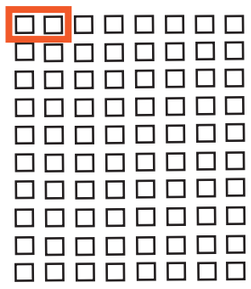


when 80 conditions are considered

To investigate this further, the prevalence of multimorbidity (≥2 conditions) in the population was calculated when considering the most common:

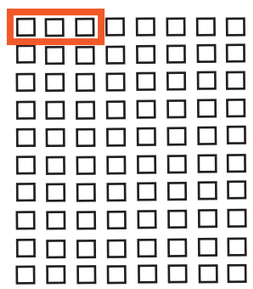


2 conditions



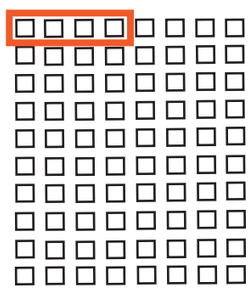
then

3 conditions



then

4 conditions



then every number up to all 80 conditions...
