

## Supporting Information

This file contains five sections:

Section 1: Supplementary Data presents additional influenza data used in the analysis, not presented in the main text.

Section 2: Supplementary Methods, presents detailed methods describing the model assumptions and analysis.

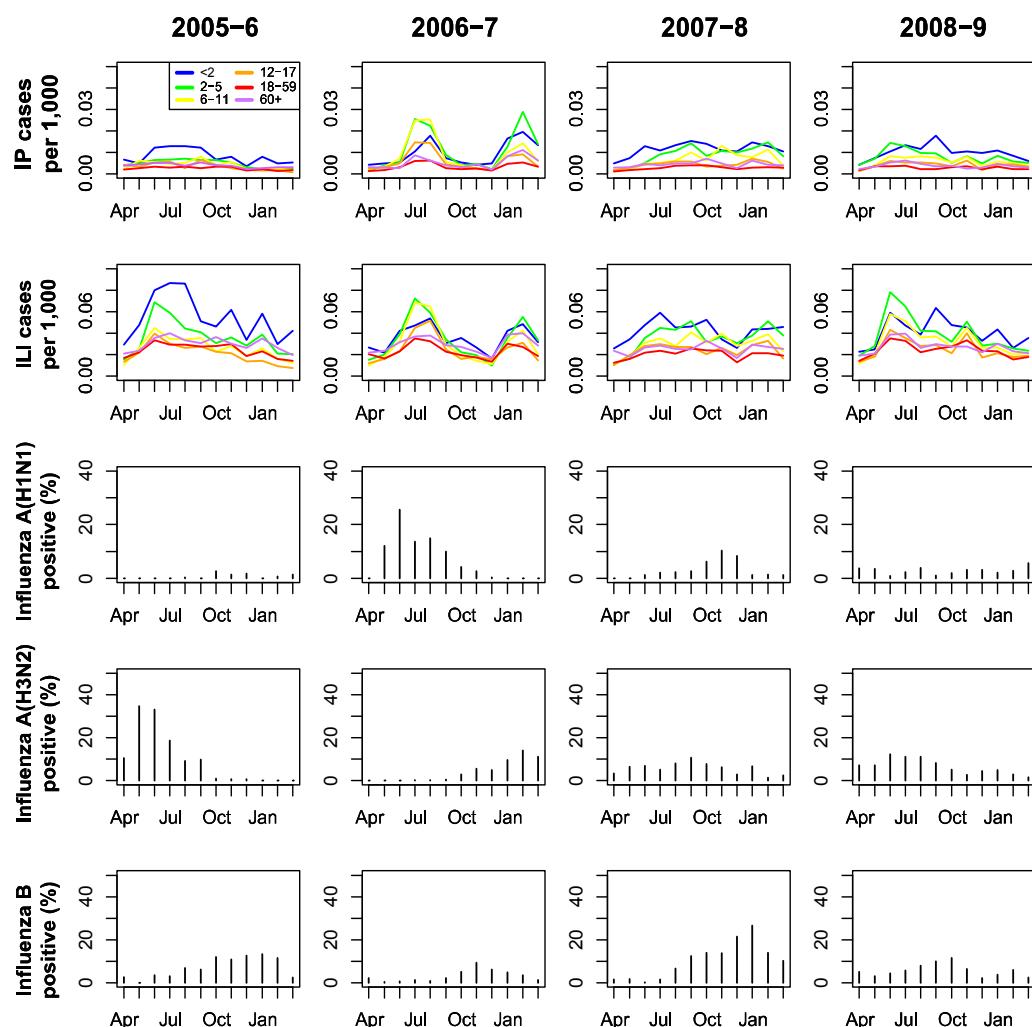

Section 3: Supplementary Results, presents additional model results.

Section 4: References for Supplementary Information.

Section 5: Model code.

### 1. Supplementary Data

S1 Figure. Monthly influenza surveillance data by age group and the proportion of tests positive for the three different influenza types from Thailand, April 2005-Mar 2009. Data shown are laboratory-confirmed influenza cases in hospital in-patients (IP), influenza like illness (ILI) in outpatients and the proportion of isolates tested that were PCR positive for A/H1N1, A/H3N2 and influenza B. IP and ILI are shown for the six age groups used in the analysis: less than two years (dark blue); 2-5 years (green); 6-11 years (yellow); 12-17 years (orange); 18-59 years (red); and ages 60 years and up (purple).

## 2. Supplementary Methods

### 2.1 Transmission and epidemiological model

The underlying transmission model consists a set of coupled ordinary differential equations

$$\begin{aligned}
 dS_i/dt &= -\lambda S_i \sum_j \beta_{ji} I_j / N_i - v_i(t) S_i / (N_i - V_i) \\
 dS_i^v/dt &= -\lambda S_i^v \sum_j \beta_{ji} I_j / N_i + v_i(t) (1 - f) S_i / (N_i - V_i) \\
 dE_i/dt &= \lambda (S_i + S_i^v) \sum_j \beta_{ji} I_j / N_i - \theta E_i \\
 dI_i/dt &= \theta E_i - \gamma I_i \\
 dR_i/dt &= \gamma I_i + v_i(t) f S_i / (N_i - V_i) \\
 dV_i/dt &= v_i(t)
 \end{aligned}$$

The model variables are:

- $S_i$  the number susceptible in age group  $i$  who have not been vaccinated;
- $S_i^v$  the number susceptible in age group  $i$  who have been vaccinated but failed to develop immunity;
- $E_i$  the number latently infected (but not yet infectious) in age group  $i$ ;
- $I_i$  the number infectious in age group  $i$ ;
- $R_i$  the number immune in age group  $i$ ;
- $V_i$  the number in age group  $i$  who have been vaccinated (whether or not they develop immunity).

The model parameters are:

- $f$  vaccine effectiveness;
- $\lambda$  the transmission scaling parameter;
- $\beta_{ji}$  elements of the contact-matrix which are proportional to rate at which a given individual in age group  $i$  makes potentially infectious contact with members of age group  $j$ ;
- $\theta$  rate of progression from latently infected to infectious;
- $\gamma$  rate of recovery from infectious state;
- $v_i(t)$  the time-varying vaccination rate in age group  $i$ .

## 2.2 Demographic data and contact data.

There were six age groups and population size estimates for these were obtained from the National Statistical Office of Thailand (S1 Table). Contact patterns between these age groups were derived from a diary-based contact survey in Thailand carried out by The International Health Policy Program, Thailand (manuscript in preparation). In the base case analysis we used all contacts. In sensitivity analysis 1 we derived the matrix using data on only physical contacts.

S1 Table: Age groups and population sizes.

Age group	Population size (N)
< 2 y	1,637,070
2-5 y	4,000,962
6-11 y	6,131,617
12-17 y	6,227,226
18-59 y	38,377,518
≥60 y	5,792,970

## 2.3 Vaccination Model

We considered both fixed and random effect models to estimate vaccine efficacy. Because the random effects model did not show any improvement in model fit (based on the deviance information criterion), we used results from the fixed effects model in all subsequent analysis:

$$c_{v,i} \sim \text{binomial}(p_{v,i}, n_{v,i})$$

$$c_{c,i} \sim \text{binomial}(p_{c,i}, n_{c,i})$$

$$\text{logit}(p_{c,i}) = m_i$$

$$\text{logit}(p_{v,i}) = m_i + \delta$$

$$\delta \sim \text{normal}(\mu_1, \sigma_1^2)$$

$$m_i \sim \text{normal}(\mu_2, \sigma_2^2)$$

$$\mu_1 \sim \text{normal}(0, 10^5)$$

$$\mu_2 \sim \text{normal}(0, 10^5)$$

$$1/\sigma_1^2 \sim \text{gamma}(0.001, 0.001)$$

$$1/\sigma_2^2 \sim \text{gamma}(0.001, 0.001)$$

$$\mu_{\text{new}} \sim \text{normal}(\mu_2, \sigma_2^2)$$

$$\text{VE} = (1 - \exp(\delta)) / (1 + \exp(\mu_2 + \delta))$$

$$\text{VE}_{\text{predict}} = (1 - \exp(\delta)) / (1 + \exp(\mu_{\text{new}} + \delta))$$

Where:

the two parameters for the gamma distribution specify the shape and rate, respectively;

$c_{v,i}$  is the number of cases in the vaccine group in study  $i$ ;

$c_{c,i}$  is the number of cases in the control group in study  $i$ ;

$n_{v,i}$  is the number of patients in the vaccine group in study  $i$ ;

$n_{c,i}$  is the number of patients in the control group in study  $i$ ;

$\delta$  is the change in the log odds of influenza infection associated with the vaccine;

$\text{VE}$  is the estimated vaccine efficacy;

$\text{VE}_{\text{predict}}$  is the predicted vaccine effectiveness in a new population.

When analysing data from cluster randomized trials, to account for clustering we used the above model, but first divided the terms  $p_{v,i}$ ,  $n_{v,i}$ ,  $p_{c,i}$ ,  $n_{c,i}$  by the design effect and rounded to the nearest integer. The design effect for a given study is equal to  $1 + (\text{mean.cluster.size} - 1) * \text{ICC}$  where the ICC is the intra-cluster correlation co-efficient.

## S2 Table

Vaccine efficacy analysis: per protocol analysis results for trials in the target age range.

Trial	Vaccine	Age group	Number vaccinated	Number of cases amongst those vaccinated <sup>1</sup>	Number in control group	Number of cases in control group <sup>1</sup>	Efficacy mean (95% CrI)
Loeb et al. 2010 <sup>2</sup>	TIV	36 months to 15 years	502	41	445	79	53.9 (35.2, 69.0)
Clover et al. <sup>3</sup>	TIV	3 to 9 years, US	30	6	33	15	54.4 (9.8, 83.1)
Meta-analysis of TIV studies in children <sup>4</sup>							48.5 (0.7, 68.9)
Predictive TIV effectiveness							46.1 (0.002, 69.7)
Belshe et al. 1998	LAIIV	15 to 71 months	849	10	410	74	93.4 (88.3, 96.8)
Belshe et al. 2000	LAIIV	26 to 85 months	917	15	441	56	86.9 (78.2, 93.0)
Meta-analysis of LAIIV studies in children							90.0 (84.9, 94.2)
Predictive LAIIV effectiveness							89.3 (80.0, 94.2)

<sup>1</sup> Including only laboratory-confirmed cases

<sup>2</sup> In this study the numbers in the table are not directly reported, but can be derived from numbers reported in the paper. Our analysis accounts for cluster effects, with the reported intra-cluster correlation co-efficient (ICC) of 0.004.

<sup>3</sup> ICC was not reported for this study, but was assumed to be equal to that reported by Loeb et al (2010).

<sup>4</sup> Two other trials evaluated TIV in children in the target age ranges (Cowling *et al.*, Clin Inf Dis 2012 and Klick *et al.*, Vaccine 2013). These were excluded from the analysis as recommendations to use two doses for children under 9 who had not been vaccinated the previous season were not reported to have been followed.

### S3 Table

Vaccine efficacy studies for LAIV used in sensitivity analysis 3, which made use only of studies conducted predominantly in Asia.

Trial	Vaccine	Age group and location	Number vaccinated	Number of cases amongst those vaccinated <sup>1</sup>	Number in control group	Number of cases in control group <sup>1</sup>	Efficacy mean (95% CrI)
Tam et al. 2007 (year 1)	LAIV	12 to <36 months	1653	81	1111	182	70.0 (61.7, 76.9)
Tam et al. 2007 (year 2) <sup>2</sup>	LAIV	12 to <36 months	503	26	494	59	56.0 (33.7, 73.0)
Lum et al. 2010	LAIV	11 to <24 months	765	23	385	32	62.6 (40.0, 79.0)
Meta-analysis of LAIV studies in Asia							67.1 (59.2, 73.7)
Predictive LAIV effectiveness							66.5 (55.9, 73.9)

<sup>1</sup> Including laboratory-confirmed cases of any influenza strain.

<sup>2</sup> Including only those who received the placebo in year 1.

#### 2.4 Observation model

Model fitting assumed that the monthly number of PCR-confirmed cases of influenza A/H1N1, A/H3N2 and B followed a multinomial distribution where the denominator was the number of PCR tests in a given month. The model assumes that the probability of a test for influenza type  $j$  in month  $i$  giving a positive result is  $p_{ij} = \max(0.01, \sigma^* l_{ij}/(N_i + \sum_j l_{ij}))$ , where  $\sigma$  is the sensitivity of the PCR test,  $l_{ij}$  is the predicted number of ILI cases due to influenza type  $j$  in month  $i$ , and  $N_i$  is the number of ILI cases not due to influenza in month  $i$ . The contribution to  $l_{ij}$  from age group  $k$  is equal to the product of the predicted number of new infections with influenza type  $j$  in month  $i$  in age group  $k$  and the age-specific probability that each infection leads to a reported ILI case,  $\rho_i$ . These reporting probabilities (which we assume to be common to all influenza types) in turn are given as the ratio of the estimated number of ILI cases due to influenza in age group  $k$ , and the number of influenza infections predicted by the model occurring age group  $k$ . The estimated number of ILI cases due to influenza in a given age group was obtained by subtracting from the observed number of ILI cases the total number of ILI cases not due to influenza. The latter was taken as the sum of the expected number of ILI cases *not* caused by influenza A/H1N1, A/H3N2 or B in each month  $i=1..12$  ( $N_i$ ). Such infections may be caused by a variety of pathogens (e.g other influenza viruses, RSV, bacterial pathogens etc). In the absence of systematic surveillance data for such pathogens, we assumed that  $N_i$  varied by age group but was constant over each 12 month period within an age group; the age and year-specific value was then taken as the minimum monthly number of ILI cases in a given year and age group. The lower bound of  $p_{ij}$  of 0.01 was imposed primarily for numerical

reasons (to avoid multinomial probabilities of zero) and corresponds to the assumption that a minimum of 1% of swabs taken from ILI cases would be confirmed positive for a given influenza subtype even in the absence of circulating influenza virus (for example due to imported cases or false positives).

## 2.5 Health outcome and cost models

Age- type- and year-specific mortality due to influenza in Thailand was estimated using a Bayesian implementation of a previously described regression approach (Goldstein *et al.*, 2012), incorporating a number of refinements (Cooper *et al*, 2015). We used 10,000,000 iterations of each model, discarding the first 1,000,000 as burn-in. Summaries of posterior distributions obtained using this approach are shown below. In the decision-model we approximated these distributions using normal distributions with the same mean and variance, as the computational burden precluded simultaneous inference in a joint model. Any samples from these distributions with negative values were replaced with zero.

S4 Table: Age- subtype and year-specific seasonal influenza mortality estimated in Thailand. Figures give estimated number deaths per 100,000 person years in each age group.

Influenza type and year	Age <18 yrs		Age 18-59 yrs		Age >59 yrs	
	mean	SD	mean	SD	mean	SD
B 2005-6	1.40	3.20	-1.21	1.54	61.42	32.82
B 2006-7	1.37	2.89	-0.84	0.94	31.64	25.48
B 2007-8	4.19	5.17	-2.84	1.99	65.34	58.03
B 2008-9	2.95	3.86	-1.71	1.73	37.66	58.69
H1N1 2005-6	0.16	0.40	0.24	0.27	11.58	10.97
H1N1 2006-7	0.80	2.88	1.83	1.10	44.95	41.68
H1N1 2007-8	0.33	2.04	1.03	0.89	134.00	61.71

## 2.7 Materials and procedure for elicitation of expert opinions

We used materials and protocols from the Sheffield Elicitation Framework (SHELF version 2, available from <http://tonyohagan.co.uk/shelf>) to elicit priors from a panel of subject-area experts, making use of both individual and group elicitation. The panel of experts comprised of four epidemiologists (all active researchers in the area) and six clinicians (all with relevant clinical experience in Thailand). Elicitation made use of the *rpanel* package in *R* version 1.12.2 (Bowman *et al.*, 2007; R Development Core Team, 2010). An example elicitation form is shown in Supplementary Figure 2.

S2 Figure: Example of an elicitation form.

<b>Quantity</b>	Attack rate (AR) of seasonal influenza
<b>Definition</b>	Proportion of persons in a population who experience influenza
<b>Evidence</b>	The Israel study estimated that the AR of seasonal influenza was between 5% to 15%. (ref.Barnea O, et al. Math BiosciEng2011) The AR of seasonal influenza in the UK and France was between 10% to 20% (ref.Truscott J, et al. J R Soc Interface 2012)

What percent of people in each age group have clinical cases of seasonal influenza		Age groups				
		0-23 months	2-4 years	5-14 years	15-59 years	>=60 years
<b>Plausible range</b>	A. Realistically, what do you think the lowest value could be?					
	A. Realistically, what do you think the highest value could be?					
<b>Median</b>	A. What would be the most likely number? (considering range fromA toB)					
<b>Lower and upper quartiles</b>	A. What would be the lower quartile? (considering range fromA toC)					
	A. What would be the lower quartile? (considering range fromC toB)					

### 3. Supplementary Results

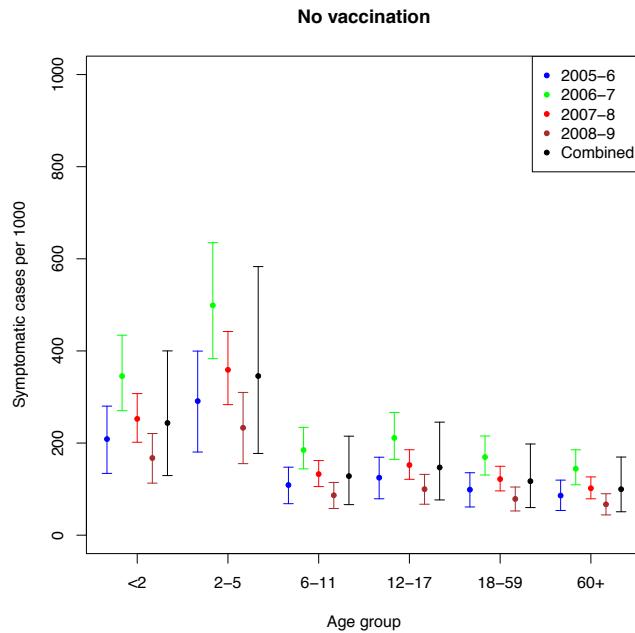

#### 3.1 Additional results from the base case model

S7 Table. Posterior distributions from base case analysis.

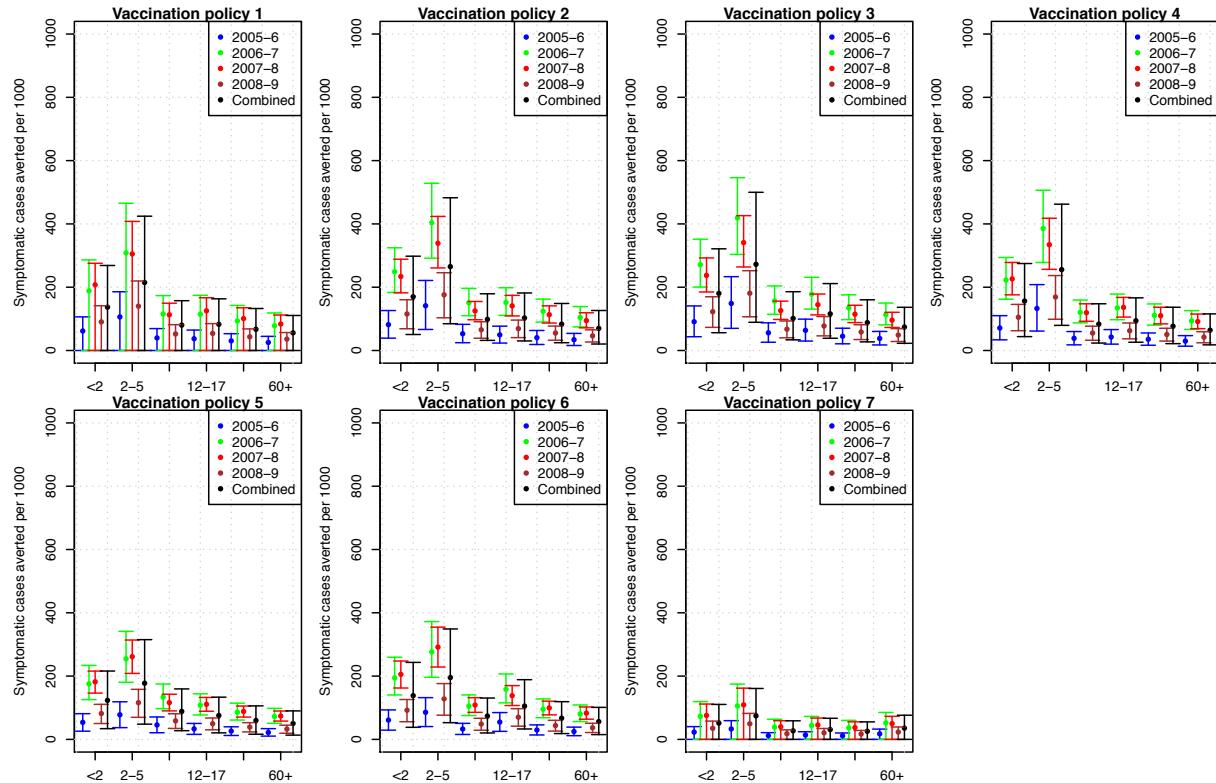

Parameter	Posterior mean (95% CrI)
$R_0$ for influenza A/ H1N1	2005-6: 0.52 (0.12, 1.07) 2006-7: 1.23 (1.17, 1.29) 2007-8: 1.16 (1.11, 1.22) 2008-9: 1.12 (1.08, 1.17)
