Text S1

Einstein’s approach to thermodynamics. In the following we present a brief outline of the derivation of Eq. (2). For detail please refer to the work cited below.

In 1910 Einstein published a paper in which he presented what has been later called (for instance by E. Schrödinger and A. Sommerfeld) „Einstein’s reversion of thermodynamics“ [39]. Einstein calls it „meaningless“ to use Boltzmann’s principle by starting from a molecular theory. Instead, Boltzmann’s principle – which he believed to be correct - has to be applied in the reversed order: One starts from the established thermodynamic phenomenology of the system and then uses it to derive the system’s fluctuations. This way, microscopic consequences can be directly derived from macroscopic observations and the second law of thermodynamics without molecular or statistical mechanics theory. The formalism of Einstein starts from a Taylor expansion of the entropy \( S \) (for simplicity here in one variable; more details can be found in [39–42]):

\[
S = S_0 + \frac{\partial S}{\partial n} (\delta n) + \frac{1}{2} \left( \frac{\partial^2 S}{\partial n^2} \right) (\delta n)^2
\]

(1)

where \( S_0 \) is the entropy maximum and \( n \) a thermodynamic variable. Combined with Boltzmann’s principle (\( k_B \) Boltzmann constant) \( P = \exp(S/k_B) \) and near equilibrium, where \( \partial S/\partial n = 0 \), this leads to a Gaussian probability distribution for the variable

\[
P(n) = C_0 \exp \left[ -\frac{\beta}{2k_B} n^2 \right]
\]

(2)

The standard deviation (thermodynamic fluctuations) of \( P(n) \) turns out to be directly proportional to the susceptibility of the system, e.g., in the case where \( n \) represents the area \( A \) of a system, to the lateral isothermal compressibility:

\[
\langle (\delta A)^2 \rangle = -k_B \left( \frac{\partial^2 S}{\partial A^2} \right)^{-1} = k_B T \cdot A \cdot \kappa_r
\]

(3)

This concept has been applied to lipid bilayers [40,43–45] as well as to lipid monolayers more recently [46].

Heimburg has combined Einstein’s approach with an Onsager type Ansatz to find a relation between heat capacity and relaxation time [33], which has been applied successfully to lipid membranes [43]. Similarly, one can demonstrate that based on a relation between area flux and corresponding thermodynamic force
\[ \frac{\partial A'}{\partial t} = L \frac{\partial S}{\partial A'} \]  

combined with a Taylor expansion of the first derivative

\[ \frac{\partial S}{\partial A} = \frac{\partial^2 S}{\partial A^2} A' \]  

and Eq. (S3), an expression between relaxation time \( \tau \) and compressibility \( \kappa \) is derived

\[ \frac{1}{\tau} = -L \left( \frac{\partial^2 S}{\partial A^2} \right)_{A_0} = \frac{L}{T \cdot A \cdot \kappa} \]  

which is identical to Eq. (2) in the manuscript.
