Deterministic model

Model without TAT and without binding of AT to DNA

As explained in the main text, the differential equations with normalized variables are the following:

\[
\begin{align*}
dm/d\tau &= \left( \frac{1}{\varepsilon} - m - (\beta - 1) \frac{x^n}{x^n + k^n} m \right), \\
da/d\tau &= -\alpha ax + \gamma m - \delta_a a, \\
dx/d\tau &= -\alpha ax + \varepsilon \left( \gamma m + \delta_{AT} y - \delta_c x \right), \\
dy/d\tau &= \alpha ax - \varepsilon (\delta_c + \delta_{AT}) y.
\end{align*}
\]

Inclusion of TAT

TAT can be introduced by adding an additional normalized variable \(z = \frac{d_m}{\varepsilon}[TAT]\) to the differential equations in the following way:
\[ m(x) = \frac{1}{\epsilon \left(1 + (\beta - 1) \frac{x^n}{\epsilon + x^n}\right)}, \]

\[ a(x) = \frac{\gamma m(x)}{\alpha x + \delta_a}, \]

\[ \frac{dx}{d\tau} = -\alpha (a(x) + y) x + \epsilon (\gamma m(x) + \delta_{AT} (y + 2z) - \delta_c x), \]

\[ \frac{dy}{d\tau} = \alpha (a(x) - y) x - \epsilon (\delta_c + \delta_{AT}) y, \]

\[ \frac{dz}{d\tau} = \alpha xy - \epsilon (\delta_c + \delta_{AT}) z. \]

As explained in the main text, \( z \) is created when \( x \) and \( y \) bind, where we assume for simplicity that this complex is created and degraded with the same rates (\( \alpha, \delta_c \) and \( \delta_{AT} \)) as \( y \). We define the total amount of toxin in the complexes, \( c = y + 2z \), resulting in the following system:

\[ m(x) = \frac{1}{\epsilon \left(1 + (\beta - 1) \frac{x^n}{\epsilon + x^n}\right)}, \]

\[ a(x) = \frac{\gamma m(x)}{\alpha x + \delta_a}, \]

\[ \frac{dx}{d\tau} = -\alpha (a(x) + y) x + \epsilon (\gamma m(x) + \delta_{AT} c - \delta_c x), \]

\[ \frac{dc}{d\tau} = \alpha (a(x) + y) x - \epsilon (\delta_c + \delta_{AT}) c. \]

**Modeling binding of AT to DNA**

To model DNA binding, we introduce additional equations to the original system. These describe the unbound DNA \([D]\) and the bound DNA \([D_{AT}]\).

\[ \frac{d[D]}{dt} = c_2[D_{AT}] - c_1[AT][D], \]

\[ \frac{d[D_{AT}]}{dt} = c_1[AT][D] - c_2[D_{AT}], \]

\[ \frac{d[M]}{dt} = r_F[D] - d_m[M] - (\beta - 1)d_m[\frac{T}{T}]^n + K^n[M], \]

\[ \frac{d[A]}{dt} = b_1[M] - a_T[A][T] - d_a[A], \]

\[ \frac{dT}{dt} = \epsilon b_1[M] - a_T[A][T] - d_c[T] + d_{a_2}[AT], \]

\[ \frac{d[AT]}{dt} = a_T[A][T] - d_{c}[AT] - d_{a_2}[AT]. \]

Hence DNA binds with AT with a rate \( c_1 = 1.28 \cdot 10^{-05} \text{ s}^{-1} \), while the unbinding occurs with a rate \( c_2 = 2.31 \cdot 10^{-03} \text{ s}^{-1} \).
Assuming $D$ and $D_{AT}$ are in equilibrium, then

$$\frac{d[D]}{dt} = c_2[D_{AT}] - c_1[AT][D] = 0,$$

$$\frac{d[D_{AT}]}{dt} = c_1[AT][D] - c_2[D_{AT}] = 0.$$  \hspace{1cm} (5)

The DNA is either bound or unbound, so that $[D] + [D_{AT}] = 1$. Using this information, then

$$[D] = \frac{c_2}{c_2 + c_1[AT]}$$  \hspace{1cm} (6)

Therefore:

$$\frac{d[M]}{dt} = r_f \frac{c_2}{c_2 + c_1[AT]} - d_m[M] - (\beta - 1)d_m \frac{[T]^a}{[T]^a + K_i^n[T]},$$

$$\frac{d[A]}{dt} = b_1[M] - a_T[A][T] - d_a[A],$$

$$\frac{d[T]}{dt} = \varepsilon b_1[M] - a_T[A][T] - d_c[T] + d_a2[AT],$$

$$\frac{d[AT]}{dt} = a_T[A][T] - d_c[AT] - d_a2[AT].$$  \hspace{1cm} (7)

After normalization we obtain the following equations:

$$\frac{dm}{d\tau} = \left( \frac{1}{\varepsilon^2 r + y} - m - (\beta - 1)\frac{x^n}{x^n + \kappa^n} m \right),$$

$$\frac{da}{d\tau} = -\alpha ax + \gamma m - \delta_a a,$$

$$\frac{dx}{d\tau} = -\alpha ax + \varepsilon (\gamma m + \delta_{AT}y - \delta_c x),$$

$$\frac{dy}{d\tau} = \alpha ax - \varepsilon (\delta_c + \delta_{AT})y.$$  \hspace{1cm} (8)

Where $r = \frac{d_{ac}c_2}{\varepsilon c_1} = 4.9$.

Assuming $m$ and $a$ are in equilibrium, this becomes:

$$m(x) = \frac{1}{\varepsilon^2 r + y} \frac{1}{\left(1 + (\beta - 1)\frac{x^n}{x^n + \kappa^n}\right)},$$

$$a(x) = \frac{\gamma m(x)}{\alpha x + \delta_a},$$

$$\frac{dx}{d\tau} = -\alpha a(x)x + \varepsilon (\gamma m(x) + \delta_{AT}y - \delta_c x),$$

$$\frac{dy}{d\tau} = \alpha a(x)x - \varepsilon (\delta_c + \delta_{AT})y.$$  \hspace{1cm} (9)
Modeling binding of AT to DNA, with TAT included.

Combining the results of the two former sections, we obtain:

\[ m(x) = \frac{r}{r + y \varepsilon \left(1 + (\beta - 1)\frac{x^n}{x^n + \varepsilon}ight)}, \]
\[ a(x) = \frac{\gamma m(x)}{\alpha x + \delta_a}, \]
\[ \frac{dx}{d\tau} = -\alpha(ax + y)x + \varepsilon(\gamma m(x) + \delta_{AT}c - \delta_c x), \]
\[ \frac{dc}{d\tau} = \alpha(ax + y)x - \varepsilon(\delta_c + \delta_{AT})c. \]

**Inclusion of growth rate slowing down and translational inhibition**

We introduce the inhibition on the translation of mRNA \( f_m \) and the inhibition of the growth \( f_t \) by using the following functions:

\[ f_m = \frac{S_m}{1 + B_m x} \]
\[ f_t = \frac{S_t}{1 + B_t x} \]

These functions are based on Cataudella et al., PLoS Computational Biology, 2013. Leaving out secondary complex formation and DNA binding, the set of differential equations then becomes:

\[ \frac{dm}{d\tau} = \left(\frac{1}{\varepsilon} - m - (\beta - 1)\frac{x^n}{x^n + \kappa^n} m\right), \]
\[ \frac{da}{d\tau} = -\alpha ax + \gamma m f_m(x) - \delta_a a, \]
\[ \frac{dx}{d\tau} = -\alpha ax + \varepsilon(\gamma m f_m(x) + \delta_{AT}y - \delta_c x f_t(x)), \]
\[ \frac{dy}{d\tau} = \alpha ax - \varepsilon(\delta_c f_t(x) + \delta_{AT})y. \]

In two dimensions this is:
\[
m = \frac{1}{\varepsilon \left(1 - (\beta - 1)\frac{e^{\alpha x}}{x^e + e^x}\right)},
\]
\[
a = \frac{ym}{\alpha x + \delta_a} f_m(x),
\]
\[
\frac{dx}{d\tau} = -\alpha ax + \varepsilon \left(\gamma m f_m(x) + \delta_{AT} y - \delta_c x f(x)\right),
\]
\[
\frac{dy}{d\tau} = \alpha ax - \varepsilon \left(\delta_c f(x) + \delta_{AT}\right)y.
\]

Note: the parameters $s_t$, $s_m$, $b_t$ and $b_m$ are linked to the parameters that we used in Eq 11 in the following way: $s_t = S_t$, $s_m = S_m$, $b_t = \frac{d_m}{e} B_t$ and $b_m = \frac{d_m}{e} B_m$.

Estimating the amplitude, period and excitation time for the stochastic simulations

First, we apply a smoothing to the timetrace for the normalized toxin concentration using the rloess method in Matlab. To estimate the duration of a toxin excitation, we take the average duration of the episodes when the smoothed normalized toxin concentration is higher than $\kappa$, the normalized threshold for the toxic effect on the mRNA. To estimate the amplitude, we take the average of the maxima of these episodes. To estimate the period, we take the average of the times between the start of each two episodes when the smoothed normalized toxin concentration is higher than $\kappa$.
