Supplemental Figure S1: Comparison of the α4β7-specific clone Act1 and the α4-specific clone 7.2R in combination with a separate β7-specific antibody.

A PBMC of healthy controls were stained with either an α4-specific antibody (clone 7.2R) in combination with a β7-specific antibody (clone FIB504) (left, green) or with the α4β7-specific antibody, clone Act1 (right, blue). Results were analysed using the Wilcoxon matched-pairs signed rank test, nonparametric test of paired samples. 

B Analysed frequencies of both staining approaches are highly correlated.
