Shown are results from linear mixed models with random intercept and time (slope):

*Model 1: included time, age, sex, baseline test score, and all possible interactions with time. The time×age interaction term allows the calculation of the yearly rate of decline by age group with reference to the <45 age group.

†Model 2: included time, age, sex, baseline test score, smoking, Townsend deprivation index, education, income, alcohol intake, physical activity, ethnicity, employment status, number of follow-up cognitive function tests completed, whether participants completed an on-line cognitive function test prior to the second follow-up (applicable to fluid intelligence and pairs matching tests only), and all possible interactions with time. The time×age interaction term allows the calculation of the yearly rate of decline by age group with reference to the <45 age group.

‡ n/a: statistical models did not converge.

§ Negative beta-coefficients for FI correspond to declines in performance compared to <45.

¶ Positive beta-coefficients for Pairs and RT correspond to declines in performance compared to <45.
